Using equation 4.4.2.3, we find that for all normal modes of H2O: $\Gamma_{\text{modes}} = 3A_1 + 1A_2 + 3B_1 + 2B_2$. Notice their are 9 irreducible representations in equation 4.4.2.4. These irreducible representations represent the symmetries of all 9 motions of the molecule: vibrations, rotations, and translations.

Vibrations or molecular orbitals that have such well-defined symmetry properties under the operations of a group are said to belong to an irreducible representation(or irrep for short). As you can see, vibrations 1and 2belong to one irrep, but 3belongs to a different one because it has a different symmetry under C2and σ_v (xz).

Group Theory is a mathematical method by which aspects of a molecules symmetry can be determined. The symmetry of a molecule reveals information about its properties (i.e., structure, spectra, polarity, chirality, etc...). Group theory can be considered the study of symmetry: the collection of symmetries of some

The framework for the study of molecular symmetry is provided by group theory, and in particular irreducible representation theory. Symmetry is useful in the study of molecular orbitals, with applications such as the Hückel method, ligand field theory, and the Woodward-Hoffmann rules. Another framework on a larger scale is the use of crystal systems to describe crystallographic symmetry in bulk materials. Many techniques for the practical assessment of molecular symmetry exist, including X ...

In mathematical parlance, $\hat{s}(yz)$ (x,y,z) = (-x,y,z). It is important to note that the choice of coordinate system is arbitrary. Convention is to always choose z to lie along the principal rotation axis. The origin may lie at the central atom or center of mass along z.
